

1 Introduction

Reasoning about programs bla bla bla

2 Programming Language

2.1 Syntax

We start by defining an imperative programming language with non deterministic choice and parametric on a set $Base$ of base commands, common choices for the set of base commands usually contain a command for assignments and boolean guards.

The set of valid \mathbb{C} programs is defined by the following inductive definition:

Definition 1 (\mathbb{C} language syntax)

$\mathbb{C} ::= \mathbb{0}$	<i>Always non terminating program</i>
$\mathbb{1}$	<i>Identity program (skip)</i>
b	<i>Base command</i>
$C_1 \mathbin{;} C_2$	<i>Program composition</i>
$C_1 + C_2$	<i>Non deterministic choice</i>
C^*	<i>Iteration</i>

Where $C, C_1, C_2 \in \mathbb{C}$ and $b \in Base$.

2.2 Semantics

Given a set \mathbb{S} of states and a family of partial functions $\llbracket b \rrbracket : \mathbb{S} \hookrightarrow \mathbb{S}$ we can define inductively the semantics of a program in \mathbb{C} by structural induction on the terms:

Definition 2 (\mathbb{C} language semantics)

$$\begin{aligned}
\llbracket \cdot \rrbracket &: \mathcal{P}(\mathbb{S}) \rightarrow \mathcal{P}(\mathbb{S}) \\
\llbracket \mathbb{0} \rrbracket &= \text{const } \emptyset \\
\llbracket \mathbb{1} \rrbracket &= id \\
\llbracket b \rrbracket &= \lambda P \rightarrow \{x \mid \llbracket b \rrbracket(p) \downarrow = x \wedge p \in P\} \\
\llbracket C_1 \mathbin{;} C_2 \rrbracket &= \llbracket C_2 \rrbracket \circ \llbracket C_1 \rrbracket \\
\llbracket C_1 + C_2 \rrbracket &= \lambda P \rightarrow \llbracket C_1 \rrbracket P \cup \llbracket C_2 \rrbracket P \\
\llbracket C^* \rrbracket &= \lambda P \rightarrow lfp(\lambda P' \rightarrow P \cup \llbracket C \rrbracket P')
\end{aligned}$$

Theorem 1 ($\llbracket \cdot \rrbracket$ is monotone) $\forall P, Q \in \mathcal{P}(\mathbb{S}) \quad C \in \mathbb{C}$

$$P \subseteq Q \implies \llbracket C \rrbracket(P) \subseteq \llbracket C \rrbracket(Q)$$

This framework is general enough to cover non deterministic imperative languages, for example if we include a base command for boolean guards $e?$ where e is a boolean valued expression on \mathbb{S} we can define the usual control flow statements **if** b **then** C_1 **else** C_2 as $(e? \circ C_1) + (\neg e? \circ C_2)$ and **while** e **do** C **done** as $(e? \circ C)^* \circ \neg e?$.

3 Best Abstract Inductive semantics

We can abstract the *Best Abstract Inductive Semantics* of a program in \mathbb{C} parametrically on a complete lattice A that has as elements collections of program states and a family of monotone functions $\llbracket b \rrbracket_{bai}^A : A \rightarrow A \quad \forall b \in Base$ by structural induction on the syntax of \mathbb{C} :

Definition 3 (Best abstract inductive semantics)

$$\begin{aligned} \llbracket \cdot \rrbracket_{bai}^A &: A \rightarrow A \\ \llbracket 0 \rrbracket_{bai}^A &= const \perp_A \\ \llbracket 1 \rrbracket_{bai}^A &= id_A \\ \llbracket b \rrbracket_{bai}^A &= \lambda P \rightarrow \llbracket b \rrbracket_{bai}^A(P) \\ \llbracket C_1 \circ C_2 \rrbracket_{bai}^A &= \llbracket C_2 \rrbracket_{bai}^A \circ \llbracket C_1 \rrbracket_{bai}^A \\ \llbracket C_1 + C_2 \rrbracket_{bai}^A &= \lambda P \rightarrow \llbracket C_1 \rrbracket_{bai}^A(P) \vee_A \llbracket C_2 \rrbracket_{bai}^A(P) \\ \llbracket C^* \rrbracket_{bai}^A &= \lambda P \rightarrow lfp(\lambda P' \rightarrow P \vee_A \llbracket C \rrbracket_{bai}^A(P')) \end{aligned}$$

Theorem 2 (Semantic equivalence) *If we take as the lattice $\mathcal{P}(\mathbb{S})$ and as $\llbracket b \rrbracket_{bai}^A = \lambda P \rightarrow \{x \mid \llbracket b \rrbracket(p) \downarrow = x \wedge p \in P\}$ the two semantics are identical.*

$$\forall P \in \mathcal{P}(\mathbb{S}) \quad C \in \mathbb{C}$$

$$\llbracket C \rrbracket_{bai}^{\mathcal{P}(\mathbb{S})}(P) = \llbracket C \rrbracket(P)$$

Theorem 3 ($\llbracket \cdot \rrbracket_{bai}^A$ is monotone) $\forall P, Q \in A \quad C \in \mathbb{C}$

$$P \leq_A Q \implies \llbracket C \rrbracket_{bai}^A(P) \leq_A \llbracket C \rrbracket_{bai}^A(Q)$$

3.1 Obtaining BAIs from other BAIs via Galois connections

Given a Galois connection $\langle D, \leq_D \rangle \xrightleftharpoons[\alpha]{\gamma} \langle A, \leq_A \rangle$ if we have define a *Best Abstract Inductive Semantics* on D with the semantics of basic commands $\llbracket b \rrbracket_{bai}^D$ we can define a *Best Abstract Inductive Semantics* on A with semantics of basic commands $\llbracket b \rrbracket_{bai}^A = \alpha \circ \llbracket b \rrbracket_{bai}^D \circ \gamma$.

Theorem 4 (Soundness) $\forall P \in D \quad C \in \mathbb{C}$

$$\alpha(\llbracket C \rrbracket_{bai}^D(P) \leq_D \llbracket C \rrbracket_{bai}^A(\alpha(P)))$$

4 Abstract Hoare logic

In this section we will define when an Abstract Hoare triple is valid, give some inference rules for it **BLAH**.

Definition 4 (Abstract Hoare triple) *Fixed a complete lattice A and the semantics of the base commands $\llbracket b \rrbracket_{bai}^A$, an Abstract Hoare triple is valid if and only if executing the bai of a command C of some precondition captured by the element P of A is overapproximated by some element Q of A :*

$$\langle P \rangle_A C \langle Q \rangle \iff \llbracket C \rrbracket_{bai}^A(P) \leq_A Q$$

4.1 Inference rule

As in standard Hoare logic we can give a set of inference rules to derive valid triples from smaller ones:

Definition 5 (Abstract Hoare inference rules) $\frac{}{\vdash \langle P \rangle_A \mathbf{0} \langle \perp \rangle} (\mathbf{0})$

$$\frac{}{\vdash \langle P \rangle_A \mathbf{1} \langle P \rangle} (\mathbf{1})$$

$$\frac{}{\vdash \langle P \rangle_A b \langle \llbracket b \rrbracket_{bai}^A(P) \rangle} (b)$$

$$\frac{\vdash \langle P \rangle_A C_1 \langle Q \rangle \quad \vdash \langle Q \rangle_A C_2 \langle R \rangle}{\vdash \langle P \rangle_A C_1 ; C_2 \langle R \rangle} (s)$$

$$\frac{\vdash \langle P \rangle_A C_1 \langle Q \rangle \quad \vdash \langle P \rangle_A C_2 \langle Q \rangle}{\vdash \langle P \rangle_A C_1 + C_2 \langle Q \rangle} (+)$$

$$\frac{\vdash \langle P \rangle_A C \langle P \rangle}{\vdash \langle P \rangle_A C^* \langle P \rangle} (*)$$

$$\frac{P \leq P' \quad \vdash \langle P' \rangle_A C \langle Q' \rangle \quad Q' \leq Q}{\vdash \langle P \rangle_A C \langle Q \rangle} (\leq)$$

Example 4.1 (Derivation in the integer interval domain) *We will start by defining our running example the integer interval domain: The elements of the interval domain on one variable are defined by $Int = \{[x, y] \mid x \leq y \text{ } x, y \in \mathbb{Z} \cup \{+\infty, -\infty\}\} \cup \{\perp\}$ where the order relation is given by $\perp \leq_{Int} a \forall a \in Int$ and $[a, b] \leq_{Int} [c, d] \iff c \leq a \wedge b \leq d$ and clearly $\top = [-\infty, +\infty]$. The definition can be lifted pointwise for domains with an arbitrary number of variables.*

As basic command we will add $e?$ for boolean tests discarding all the states that don't satisfy the condition e and $x := y$ assigning the result of evaluating expression y to the variable x and fix $\llbracket b \rrbracket_{bai}^A = \alpha \circ \llbracket b \rrbracket \circ \gamma$.

Then the following is a valid derivation for program $C = (x := 1 + x := 2) \circ x := x + 1$

$$\frac{\frac{\frac{\top \leq \top \quad \vdash \langle \top \rangle_A x := 1 \langle x \in [1, 1] \rangle \quad x \in [1, 1] \leq x \in [1, 2]}{\vdash \langle \top \rangle_A x := 1 \langle x \in [1, 2] \rangle} \quad \frac{\top \leq \top \quad \vdash \langle \top \rangle_A x := 2 \langle x \in [2, 2] \rangle \quad x \in [2, 2] \leq x \in [1, 2]}{\vdash \langle \top \rangle_A x := 2 \langle x \in [1, 2] \rangle}}{\vdash \langle \top \rangle_A x := 1 + x := 2 \langle x \in [1, 2] \rangle} \quad \frac{\vdash \langle \top \rangle_A C \langle x \in [2, 3] \rangle}{\vdash \langle \top \rangle_A C \langle x \in [2, 3] \rangle} \quad \vdash \langle x \in [1, 2] \rangle_A x := x + 1 \langle x \in [2, 3] \rangle$$

And clearly $\llbracket C \rrbracket_{bai}^A(\top) = x \in [2, 3]$.

Theorem 5 (The proofs system is sound)

$$\vdash \langle P \rangle_A C \langle Q \rangle \implies \langle P \rangle_A C \langle Q \rangle$$

Proof 1 By structural induction on the last rule applied in the derivation of $\vdash \langle P \rangle_A C \langle Q \rangle$:

- (0): Then the last step in the derivation was:

$$\frac{}{\vdash \langle P \rangle_A \mathbf{0} \langle \perp \rangle} \text{ (0)}$$

The triple is valid since:

$$\llbracket \mathbf{0} \rrbracket_{bai}^A(P) = \perp_A \quad \text{By definition of } \llbracket \cdot \rrbracket_{bai}^A$$

- (1): Then the last step in the derivation was:

$$\frac{}{\vdash \langle P \rangle_A \mathbf{1} \langle P \rangle} \text{ (1)}$$

The triple is valid since:

$$\llbracket \mathbf{1} \rrbracket_{bai}^A(P) = P \quad \text{By definition of } \llbracket \cdot \rrbracket_{bai}^A$$

- (b): Then the last step in the derivation was:

$$\frac{}{\vdash \langle P \rangle_A b \langle \llbracket b \rrbracket_{bai}^A(P) \rangle} \text{ (b)}$$

The triple is valid since:

$$\llbracket b \rrbracket_{bai}^A(P) = \llbracket b \rrbracket_{bai}^A(P) \quad \text{By definition of } \llbracket \cdot \rrbracket_{bai}^A$$

- (\circ): Then the last step in the derivation was:

$$\frac{\vdash \langle P \rangle_A C_1 \langle Q \rangle \quad \vdash \langle Q \rangle_A C_2 \langle R \rangle}{\vdash \langle P \rangle_A C_1 \circ C_2 \langle R \rangle} \text{ (\circ)}$$

By inductive hypothesis: $\llbracket C_1 \rrbracket_{bai}^A(P) \leq_A Q$ and $\llbracket C_2 \rrbracket_{bai}^A(Q) \leq_A R$.

The triple is valid since:

$$\begin{aligned} \llbracket C_1 \circ C_2 \rrbracket_{bai}^A(P) &= \llbracket C_2 \rrbracket_{bai}^A(\llbracket C_1 \rrbracket_{bai}^A(P)) && \text{By definition of } \llbracket \cdot \rrbracket_{bai}^A \\ &\leq_A \llbracket C_2 \rrbracket_{bai}^A(Q) && \text{By monotonicity of } \llbracket \cdot \rrbracket_{bai}^A \\ &\leq_A R \end{aligned}$$

- (+): Then the last step in the derivation was:

$$\frac{\vdash \langle P \rangle_A C_1 \langle Q \rangle \quad \vdash \langle P \rangle_A C_2 \langle Q \rangle}{\vdash \langle P \rangle_A C_1 + C_2 \langle Q \rangle} (+)$$

By inductive hypothesis: $\llbracket C_1 \rrbracket_{bai}^A(P) \leq Q$ and $\llbracket C_2 \rrbracket_{bai}^A(P) \leq Q$.

The triple is valid since:

$$\begin{aligned} \llbracket C_1 + C_2 \rrbracket_{bai}^A(P) &= \llbracket C_1 \rrbracket_{bai}^A(P) \vee \llbracket C_2 \rrbracket_{bai}^A(P) && \text{By definition of } \llbracket \cdot \rrbracket_{bai}^A \\ &\leq_A Q \vee Q \\ &= Q \end{aligned}$$

- (★): Then the last step in the derivation was:

$$\frac{\vdash \langle P \rangle_A C \langle P \rangle}{\vdash \langle P \rangle_A C^\star \langle P \rangle} (*)$$

By inductive hypothesis: $\llbracket C \rrbracket_{bai}^A P \leq P$

$$\llbracket C^\star \rrbracket_{bai}^A(P) = \text{lf}p(\lambda P' \rightarrow P \vee_A \llbracket C \rrbracket_{bai}^A(P'))$$

$$\begin{aligned} (\lambda P' \rightarrow P \vee_A \llbracket C \rrbracket_{bai}^A(P'))(P) &= P \vee \llbracket C \rrbracket_{bai}^A(P) \quad \text{since } \llbracket C \rrbracket_{bai}^A(P) \leq P \\ &= P \end{aligned}$$

Hence P is a fixpoint for $\lambda P' \rightarrow P \vee_A \llbracket C \rrbracket_{bai}^A(P')$

Thus $\text{lf}p(\lambda P' \rightarrow P \vee_A \llbracket C \rrbracket_{bai}^A(P')) \leq_A P$

- (\leq): Then the last step in the derivation was:

$$\frac{P \leq P' \quad \vdash \langle P' \rangle_A C \langle Q' \rangle \quad Q' \leq Q}{\vdash \langle P \rangle_A C \langle Q \rangle} (\leq)$$

By inductive hypothesis: $\llbracket C \rrbracket_{bai}^A(P') \leq Q'$.

$$\begin{array}{ll} \llbracket C \rrbracket_{bai}^A(P) \llbracket C \rrbracket_{bai}^A(P') & \text{By monotonicity of } \llbracket \cdot \rrbracket_{bai}^A \\ \leq Q' & \text{By inductive hypothesis} \\ \leq Q & \end{array}$$

4.2 Merge rules

In standard Hoare logic the following rule is valid:

$$\frac{\vdash \{P_1\} C \{Q\} \quad \vdash \{P_2\} C \{Q\}}{\vdash \{P_1 \vee P_2\} C \{Q\}} \text{ (merge)}$$

And can be used to easily merge the results obtained by different analysis, but in general the same rule in the context of abstract Hoare logic:

$$\frac{\vdash \langle P_1 \rangle_A C \langle Q \rangle \quad \vdash \langle P_2 \rangle_A C \langle Q \rangle}{\vdash \langle P_1 \vee P_2 \rangle_A C \langle Q \rangle} \text{ (merge)}$$

is unsound.

Example 4.2 (Unsoundness of the rule (merge)) Let A and $\llbracket b \rrbracket_{bai}^A$ be the same as in 4.1 and $C = (x = 3? \text{ } x := 400) + (x \neq 3? \text{ } x := x + 1)$

Then we can derive the following triples:

- $\vdash \langle x \in [1, 2] \rangle_A C \langle x \in [2, 3] \rangle$
- $\vdash \langle x \in [4, 5] \rangle_A C \langle x \in [5, 6] \rangle$

But applying the rule (merge) would allow to derive the following: $\vdash \langle x \in [1, 5] \rangle_A C \langle x \in [2, 6] \rangle$, that is unsound since $\llbracket C \rrbracket_{bai}^A(x \in [1, 5]) = x \in [2, 400]$.

The cause of the issue is caused by the non additivity of the base commands, in fact:

Theorem 6 (Additivity of the semantics on additive base commands)
if $\forall P_1, P_2 \in A$ and $b \in \text{Base}$ $\llbracket B \rrbracket_{bai}^A(P_1 \vee P_2) = \llbracket B \rrbracket_{bai}^A(P_1) \vee \llbracket B \rrbracket_{bai}^A(P_2)$ then:
 $\forall P_1, P_2 \in A \quad C \in \mathbb{C}$

$$\llbracket C \rrbracket_{bai}^A(P_1) \vee \llbracket C \rrbracket_{bai}^A(P_2) = \llbracket C \rrbracket_{bai}^A(P_1 \vee P_2)$$

Proof 2 By structural induction on C :

- 0 : By definition $\llbracket 0 \rrbracket_{bai}^A(P_1 \vee P_2) = \perp$ and $\llbracket 0 \rrbracket_{bai}^A(P_i) = \perp$
- 1 : By definition $i \in \{1, 2\}$ $\llbracket 1 \rrbracket_{bai}^A(P_i) = P_i$ and $\llbracket 1 \rrbracket_{bai}^A(P_1 \vee P_2) = P_1 \vee P_2$

- b :

$$\llbracket b \rrbracket_{bai}^A(P_1 \vee P_2) = \llbracket b \rrbracket_{bai}^A(P_1) \vee \llbracket b \rrbracket_{bai}^A(P_2) \quad \text{By additivity of } \llbracket b \rrbracket_{bai}^A$$

- $C_1 \circ C_2$:

$$\begin{aligned} \llbracket C_1 \circ C_2 \rrbracket_{bai}^A(P_1 \vee P_2) &= \llbracket C_2 \rrbracket_{bai}^A(\llbracket C_1 \rrbracket_{bai}^A(P_1 \vee P_2)) \\ &= \llbracket C_2 \rrbracket_{bai}^A(\llbracket C_1 \rrbracket_{bai}^A(P_1) \vee \llbracket C_1 \rrbracket_{bai}^A(P_2)) \quad \text{By inductive hypothesis} \\ &= \llbracket C_1 \circ C_2 \rrbracket_{bai}^A(P_1) \vee \llbracket C_1 \circ C_2 \rrbracket_{bai}^A(P_2) \\ &\quad \text{By inductive hypothesis} \end{aligned}$$

- $C_1 + C_2$:

$$\begin{aligned} \llbracket C_1 + C_2 \rrbracket_{bai}^A(P_1 \vee P_2) &= \llbracket C_1 \rrbracket_{bai}^A(P_1 \vee P_2) \vee \llbracket C_2 \rrbracket_{bai}^A(P_1 \vee P_2) \\ &= \llbracket C_1 \rrbracket_{bai}^A(P_1) \vee \llbracket C_2 \rrbracket_{bai}^A(P_2) \vee \llbracket C_2 \rrbracket_{bai}^A(P_1) \vee \llbracket C_2 \rrbracket_{bai}^A(P_2) \quad \text{By inductive hypothesis} \\ &= \llbracket C_1 + C_2 \rrbracket_{bai}^A(P_1) \vee \llbracket C_1 + C_2 \rrbracket_{bai}^A(P_2) \quad \text{Rearranging } \vee \text{ and by d} \end{aligned}$$

- C^* :

$$\llbracket C^* \rrbracket_{bai}^A(P_1 \vee P_2) = \text{lf}p(\lambda P' \rightarrow P_1 \vee P_2 \vee \llbracket C \rrbracket_{bai}^A(P'))$$

$$\text{Let } F_i = \text{lf}p(\lambda P' \rightarrow P_i \vee \llbracket C \rrbracket_{bai}^A(P'))$$

$$\begin{aligned} (\lambda P' \rightarrow P_1 \vee P_2 \vee_A \llbracket C \rrbracket_{bai}^A(P'))(F_1 \vee F_2) &= P_1 \vee P_2 \vee \llbracket C \rrbracket_{bai}^A(F_1 \vee F_2) \\ &= P_1 \vee P_2 \vee \llbracket C \rrbracket_{bai}^A(F_1) \vee \llbracket C \rrbracket_{bai}^A(F_2) \quad \text{By inductive hypothesis} \\ &= P_1 \vee \llbracket C \rrbracket_{bai}^A(F_1) \vee P_2 \vee \llbracket C \rrbracket_{bai}^A(F_2) \\ &= F_1 \vee F_2 \end{aligned}$$

Thus $F_1 \vee F_2$ is a fixpoint for $\lambda P' \rightarrow P_i \vee \llbracket C \rrbracket_{bai}^A(P')$.

Following the same reasoning is also the least one by $F_1 \vee F_2$ being the smallest $K \geq F_1$ and $K \geq F_2$

Theorem 7 (Soundness of the rule merge on attitive base commands)
if $\forall P_1, P_2 \in A$ and $b \in \text{Base}$ $\llbracket B \rrbracket_{bai}^A(P_1 \vee P_2) = \llbracket B \rrbracket_{bai}^A(P_1) \vee \llbracket B \rrbracket_{bai}^A(P_2)$ then:
 $\forall P_2, P_2, Q \in A \quad C \in \mathbb{C}$

$$\llbracket C \rrbracket_{bai}^A(P_1) \leq Q \text{ and } \llbracket C \rrbracket_{bai}^A(P_2) \leq Q \implies \llbracket C \rrbracket_{bai}^A(P_1 \vee P_2) \leq Q$$

Proof 3 Let $S_i = \llbracket C \rrbracket_{bai}^A(P_i)$ by Theorem 4.2 $\llbracket C \rrbracket_{bai}^A(P_1 \vee P_2) = \llbracket C \rrbracket_{bai}^A(P_1) \vee \llbracket C \rrbracket_{bai}^A(P_2) \leq Q \vee Q = Q$

But requiring all the base commands to be additive is a strong requirement with $\mathcal{P}(\mathbb{S})$ the requirement is equivalent as requiring γ especially when the base commands are defined through a Galois connection to be additive, a requirement satisfied by a very small portion of abstract domains utilized in practice.

Theorem 8 (Base commands additivity) Given a Galois connection $\langle D, \leq_D \rangle \xrightarrow[\alpha]{\gamma} \langle A, \leq_A \rangle$ and $\llbracket b \rrbracket_{bai}^D$ additive.

$$\alpha \circ \llbracket b \rrbracket_{bai}^D \circ \gamma \text{ additive} \iff \gamma \text{ additive}$$

Proof 4

$$\begin{aligned} \alpha(\llbracket b \rrbracket_{bai}^A(\gamma(P_1 \vee P_2))) &= \alpha(\llbracket b \rrbracket_{bai}^A(\gamma(P_1) \vee \gamma(P_2))) \\ &= \alpha(\llbracket b \rrbracket_{bai}^A(\gamma(P_1)) \vee \llbracket b \rrbracket_{bai}^A(\gamma(P_2))) \\ &= \alpha(\llbracket b \rrbracket_{bai}^A(\gamma(P_1))) \vee \alpha(\llbracket b \rrbracket_{bai}^A(\gamma(P_2))) \end{aligned}$$

4.2.1 Local condition

Given that additivity conditions on the domain A are too restrictive we will look at local conditions.

One could think that requiring γ to be additive on $P_1 \vee P_2$ is enough giving a rule like this:

$$\frac{\vdash \langle P_1 \rangle_A C \langle Q \rangle \quad \vdash \langle P_2 \rangle_A C \langle Q \rangle \quad \gamma(P_1 \vee P_2) = \gamma(P_1) \vee \gamma(P_2)}{\vdash \langle P_1 \vee P_2 \rangle_A C \langle Q \rangle} \text{ (merge)}$$

Example 4.3 ((merge) rule is unsound) Let A and $\llbracket b \rrbracket_{bai}^A$ be the same as in 4.1.

By picking $P_1 = x \in [0, 1]$ and $P_2 = x \in [2, 2]$ we can obtain the following judgments:

- $\langle P_1 \rangle_A C \langle \perp \rangle$
- $\langle P_2 \rangle_A C \langle \perp \rangle$

And by applying the (merge) rule we can obtain: $\langle P_1 \vee P_2 \rangle_A C \langle Q \rangle$ but by running command C on $P_1 \vee P_2$ we obtain $x \in [1, 1]$.

$$\begin{aligned}
\llbracket C \rrbracket_{bai}^A(P_1 \vee P_2) &= \llbracket C \rrbracket_{bai}^A(x \in [0, 2]) \\
&= \llbracket x = 1? \rrbracket_{bai}^A(\llbracket x = 0? + x = 2? \rrbracket_{bai}^A(x \in [0, 2])) \\
&= \llbracket x = 1? \rrbracket_{bai}^A(\llbracket x = 0? \rrbracket_{bai}^A(x \in [0, 2]) \vee \llbracket x = 2? \rrbracket_{bai}^A(x \in [0, 2])) \\
&= \llbracket x = 1? \rrbracket_{bai}^A(x \in [0, 0]) \vee (x \in [2, 2]) \\
&= \llbracket x = 1? \rrbracket_{bai}^A(x \in [0, 2]) \\
&= x \in [1, 1]
\end{aligned}$$

The issue is caused by the imprecision added by the \vee introduced by the non deterministic choice.

In fact the following equivalence between programs that is true on the concrete domain $(C_1 + C_2) \circ C_3 \equiv (C_1 \circ C_3) + (C_2 \circ C_3)$ it's not true in the abstract, the program $C' = (x = 0? \circ x = 1?) + (x = 2? \circ x = 1?)$ that should be equivalent to C it's not: $\llbracket C' \rrbracket_{bai}^A(P_1 \vee P_2) = \perp$.

The fact that programs C and C' are different when interpreted by $\llbracket \cdot \rrbracket_{bai}^A$ means that we can't look at them as a KAT, in fact this would violate the axiom $(p+q)r = pr+qr$. It should also be noted that the dual axiom $r(p+q) = rp+rq$ instead holds.

Theorem 9 $\forall C_1 C_2 C_3$

$$\llbracket C_1 \circ (C_2 + C_3) \rrbracket_{bai}^A = \llbracket (C_1 \circ C_2) + (C_1 \circ C_3) \rrbracket_{bai}^A$$

Proof 5

$$\begin{aligned}
\llbracket C_1 \circ (C_2 + C_3) \rrbracket_{bai}^A(P) &= \llbracket C_2 \rrbracket_{bai}^A(\llbracket C_1 \rrbracket_{bai}^A(P)) \vee \llbracket C_3 \rrbracket_{bai}^A(\llbracket C_1 \rrbracket_{bai}^A(P)) \\
&= \llbracket C_1 \circ C_2 \rrbracket_{bai}^A(P) \vee \llbracket C_1 \circ C_3 \rrbracket_{bai}^A(P) \\
&= \llbracket C_1 \circ C_2 + C_1 \circ C_3 \rrbracket_{bai}^A(P)
\end{aligned}$$

Requiring $(C_1 + C_2) \circ C_3 \equiv (C_1 \circ C_3) + (C_2 \circ C_3)$ is equivalent to requiring the abstract semantics of every program to be additive:

Theorem 10

$$\forall C_1 C_2 C_3 \quad \llbracket (C_1 + C_2) \circ C_3 \rrbracket_{bai}^A = \llbracket (C_1 \circ C_3) + (C_2 \circ C_3) \rrbracket_{bai}^A$$

$$\iff$$

$$\forall P_1 P_2 (\text{decidable}) C' \quad \llbracket C' \rrbracket_{bai}^A(P_1 \vee P_2) = \llbracket C_1 \rrbracket_{bai}^A(P_1) \vee \llbracket C_2 \rrbracket_{bai}^A(P_2)$$

Proof 6 • (\iff):

$$\begin{aligned}
\llbracket (C_1 + C_2) \circ C_3 \rrbracket_{bai}^A(P) &= \llbracket C_3 \rrbracket_{bai}^A(\llbracket C_1 \rrbracket_{bai}^A(P) \vee \llbracket C_2 \rrbracket_{bai}^A(P)) \\
&= \llbracket C_3 \rrbracket_{bai}^A(\llbracket C_1 \rrbracket_{bai}^A(P)) \vee \llbracket C_3 \rrbracket_{bai}^A(\llbracket C_2 \rrbracket_{bai}^A(P)) \\
&= \llbracket (C_1 \circ C_3) + (C_2 \circ C_3) \rrbracket_{bai}^A(P)
\end{aligned}$$

- (\implies): For every proposition P we can construct a program $c(P)$ such that $\llbracket c(P) \rrbracket_{bai}^A(Q) = P$ (we just need to provide a program for every join-irreducible element in A)

$$\begin{aligned}
\llbracket C \rrbracket_{bai}^A(P_1 \vee P_2) &= \llbracket C \rrbracket_{bai}^A(\llbracket c(P_1) \rrbracket_{bai}^A(Q) \vee \llbracket c(P_2) \rrbracket_{bai}^A(Q)) \\
&= \llbracket C \rrbracket_{bai}^A(\llbracket c(P_1) + c(P_2) \rrbracket_{bai}^A(Q)) \\
&= \llbracket (c(P_1) + c(P_2)) \circ C \rrbracket_{bai}^A(Q) \\
&= \llbracket (c(P_1) \circ C) + (c(P_2) \circ C) \rrbracket_{bai}^A(Q) \\
&= \llbracket C \rrbracket_{bai}^A(\llbracket c(P_1) \rrbracket_{bai}^A(Q)) \vee \llbracket C \rrbracket_{bai}^A(\llbracket c(P_2) \rrbracket_{bai}^A(Q)) \\
&= \llbracket C \rrbracket_{bai}^A(P_1) \vee \llbracket C \rrbracket_{bai}^A(P_2)
\end{aligned}$$
